This animation shows both the compressed air and refrigeration circuits within a Parker PRD Series air dryer. A unique plate heat exchanger is used to pre-heat the incoming compressed air before it enters the refrigeration cycle. This is a common feature in refrigerated air dryers to improve efficiency and reduce the load on the compressor. The refrigeration cycle typically uses a refrigerant like R134a or R407C. The cycle consists of a compressor, condenser, expansion valve, and evaporator. The evaporator is located inside the air dryer and cools the compressed air, causing moisture to condense and be removed. The condenser is located outside the air dryer and rejects heat to the ambient air. The expansion valve controls the flow of refrigerant between the condenser and the evaporator. The evaporator also acts as a moisture trap, collecting any remaining moisture in the compressed air. The refrigerated air dryers are the most common and cost-effective means of treating compressed air. They use a refrigeration cycle to cool the compressed air and remove moisture. They are typically used in industrial and commercial applications where high-quality compressed air is required. They are also used in residential applications for protecting sensitive equipment from moisture damage. They are a reliable and efficient way to ensure that your compressed air is clean and dry. They are also relatively easy to maintain and repair. They are a great investment for anyone who needs high-quality compressed air.
